INSTITUTE**

Recap and where we're at

- IND-CPA secure blockcipher modes of operation
 - CTR mode, CBC mode
 - Message confidentiality under chosen-plaintext attacks
- Limitations of encryption just being IND-CPA
 - Does not provide integrity
 - Does not provide confidentiality under chosen-*ciphertext* attacks (CCAs)
- Today: confidentiality-breaking CCAs

Integrity attack setting

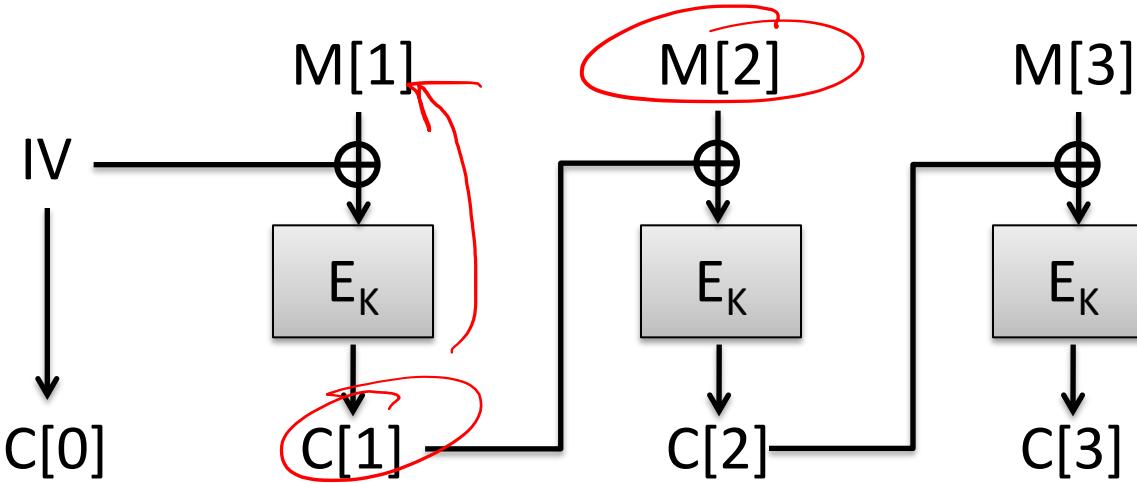

Adversary's goal:

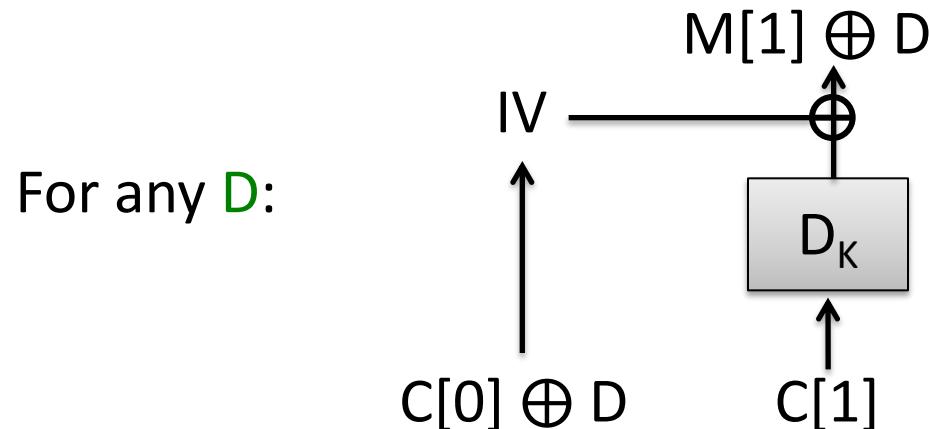

- get recipient to accept $M' \neq M$
- compromises integrity of some application

What are some settings where integrity is important?

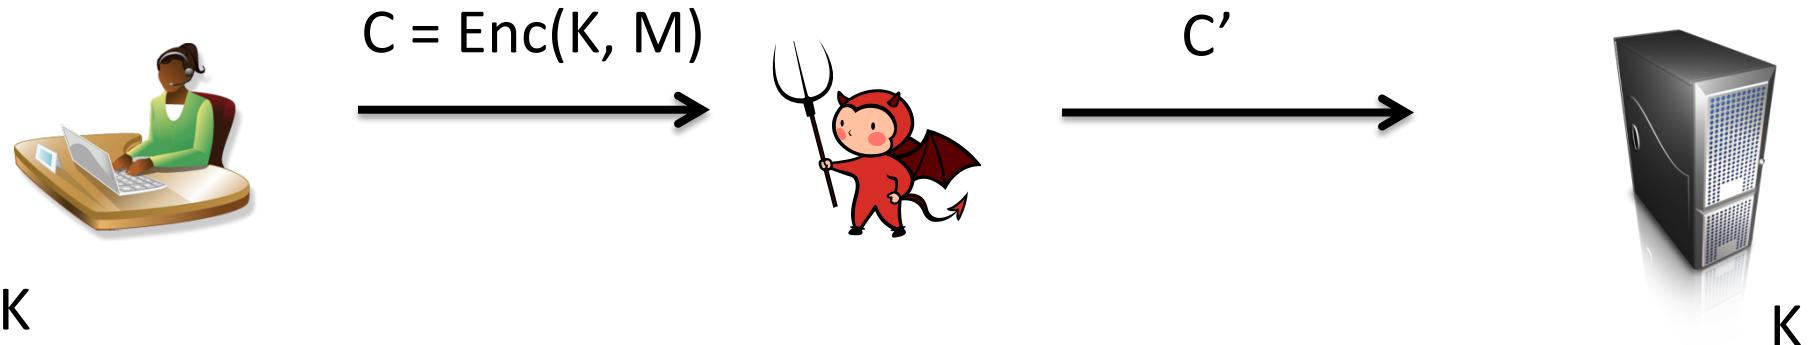

CBC mode has malleability issues, too

How do we change bits of M received by server?

Integrity attack setting

Adversary's goal:

- get recipient to accept $M' \neq M$
- compromises integrity of some application

$M' \leftarrow \text{Dec}(K, C')$
If $M' \neq \perp$ then
 Pass M' to application
Return error

Do any of the schemes we've seen so far prevent integrity attacks?

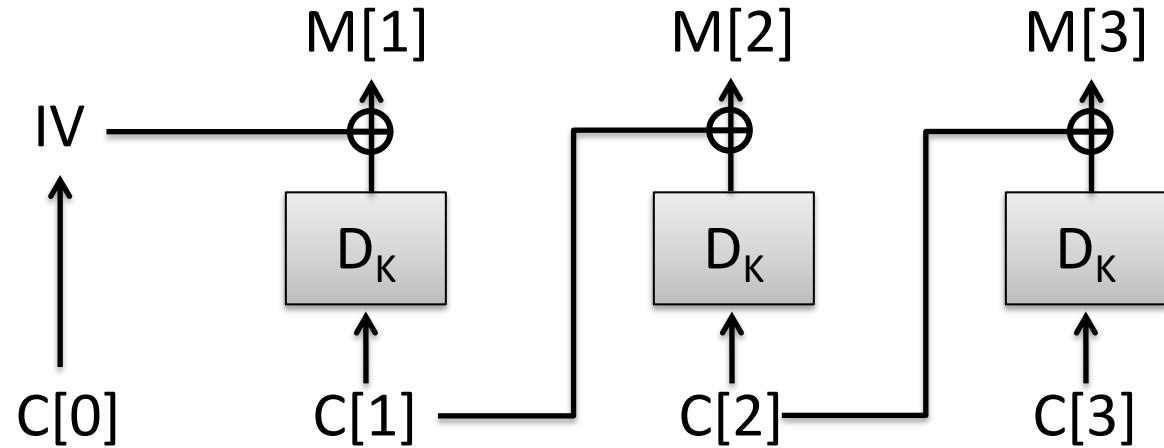

All schemes accept any appropriate-length bit string as valid ciphertext!

Decryption errors

In implementation, what to do when CBC decryption called on bit string that isn't a multiple of n?

Throw an exception or return an error

In pseudocode, cryptographers often denote this by returning the bottom symbol \perp

Padding for CBC mode

- CBC mode handles messages with length a multiple of n bits
- We use padding to make it work for arbitrary message lengths
 - PadCBC, UnpadCBC map to, from strings of length multiple of n
- Padding checks often give rise to chosen-ciphertext attack called ***padding oracle attacks***
 - Given CBC mode encryption $C = \text{Enc}(K, M)$ for unknown M
 - Access to oracle that reveals just whether decryption succeeds
 - Recover M

Pseudocode for CBC mode with padding

Kg():

$K \leftarrow \$_{0,1}^k$

CBC-Enc(K,M):

$L \leftarrow |M| ; m \leftarrow \text{ceil}(L/n)$

$C[0] \leftarrow IV \leftarrow \$_{0,1}^n$

$M[1], \dots, M[m] \leftarrow \text{PadCBC}(M, n)$

For $i = 1$ to m do

$C[i] \leftarrow E_K(C[i-1] \oplus M[i])$

Return $C[0] \parallel C[1] \parallel \dots \parallel C[m]$

Pick a random key

PadCBC unambiguously pads M to a sequence of n bit message blocks

CBC-Dec(K,C):

For $i = 1$ to m do

$M[i] \leftarrow C[i-1] \oplus D_K(C[i])$

$M \leftarrow \text{UnpadCBC}(M[1], \dots, M[m], n)$

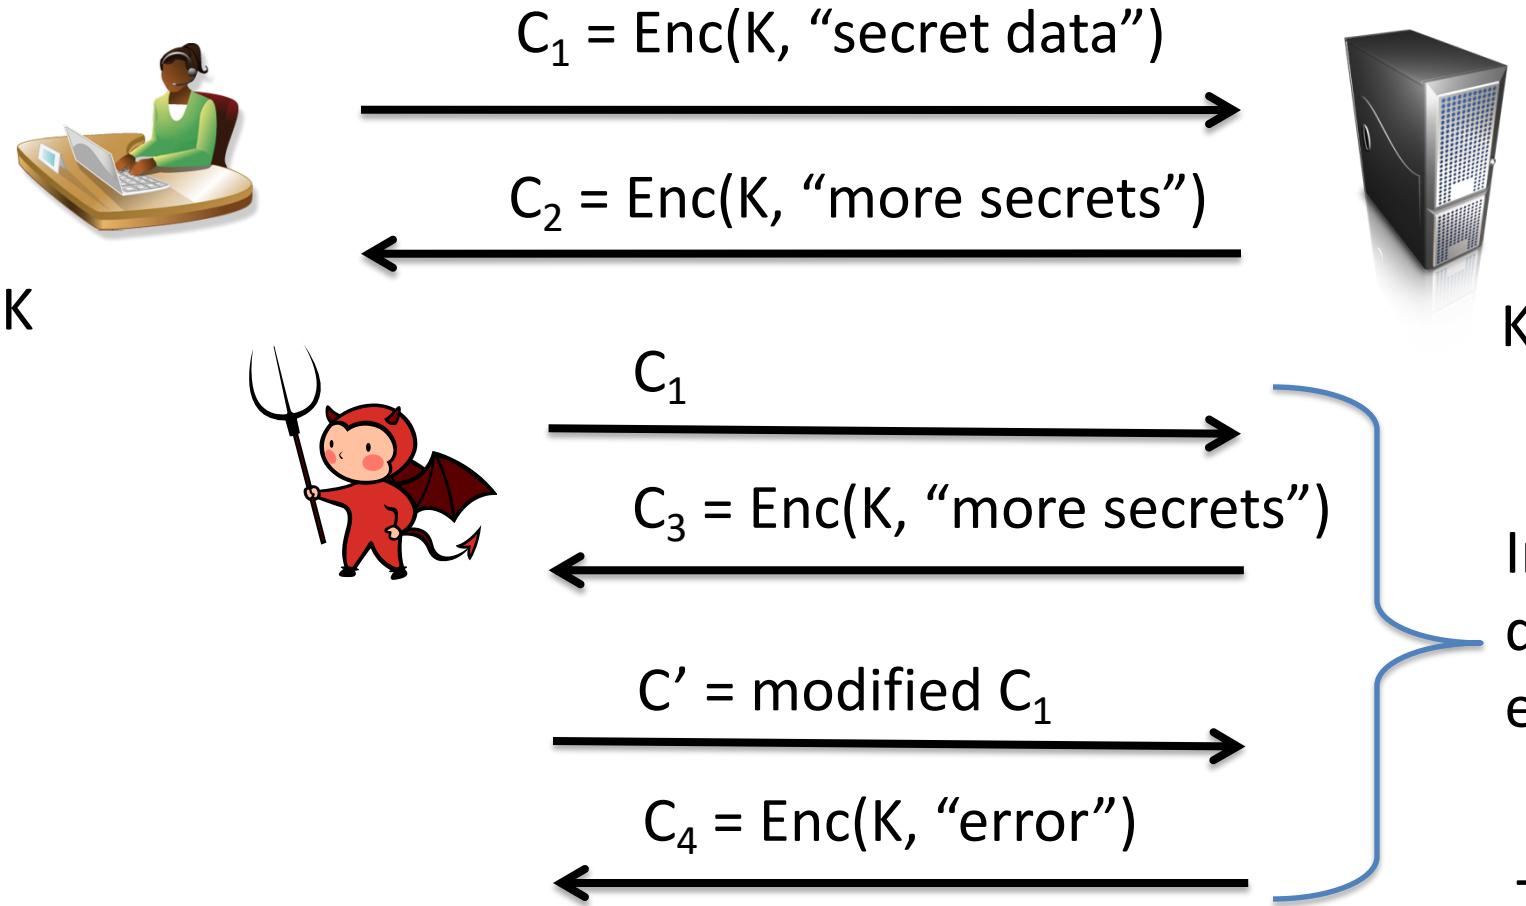

Return M

UnpadCBC removes padding, returns appropriately long string

May output **error** if padding is wrong

In crypto, errors often denoted by \perp

Partial decryption oracles arise frequently in practice

Examples:

TLS/HTTPS partial decryption oracle for network adversaries

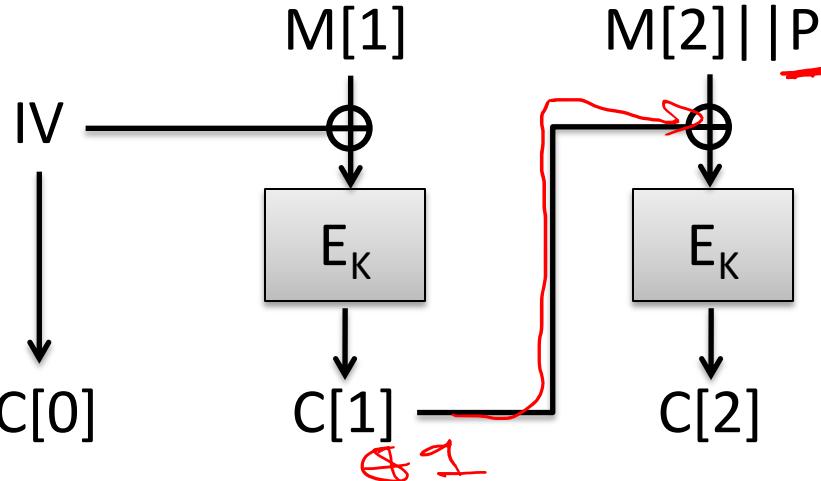

Cookies as symmetric ciphertexts for malicious clients

In practice usually easy to distinguish C_3 from C_4 even without K

$$|C_4| \neq |C_3|$$

Timing differs for successful vs. unsuccessful decryption

Simple situation: pad by 1 byte

Assume that
 $M[1] \parallel M[2]$ has length
2n-8 bits

P is one byte of padding
that must equal 0x00

Adversary
obtains
ciphertext
 $C[0], C[1], C[2]$

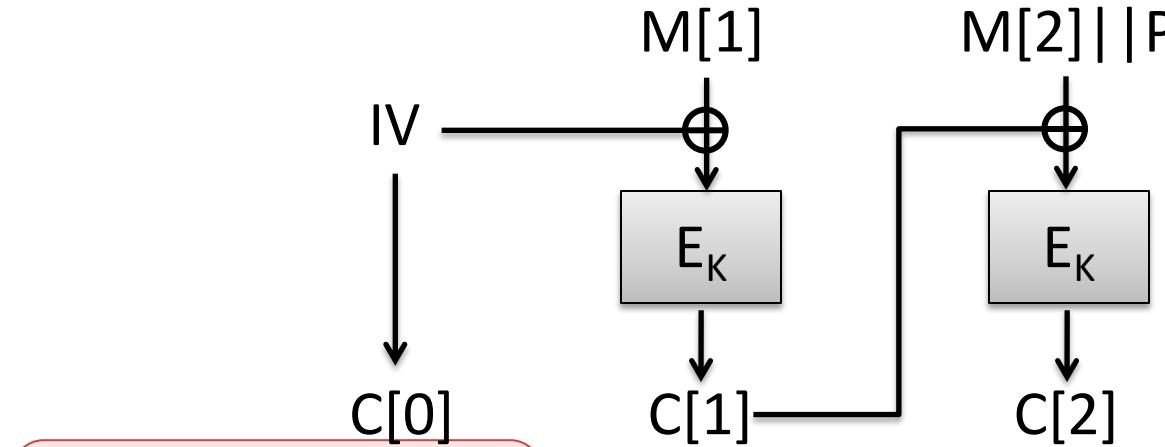

$C[0], C[1], C[2]$
ok

$C[0], C[1] \oplus 1, C[2]$
error

Dec(K, C')
 $M'[1] \parallel M'[2] \parallel P' = \text{CBC-Dec}(K, C')$
If $P' \neq 0x00$ then
Return error
Else
Return ok

Simple situation: pad by 1 byte

Low byte of M1 equals i

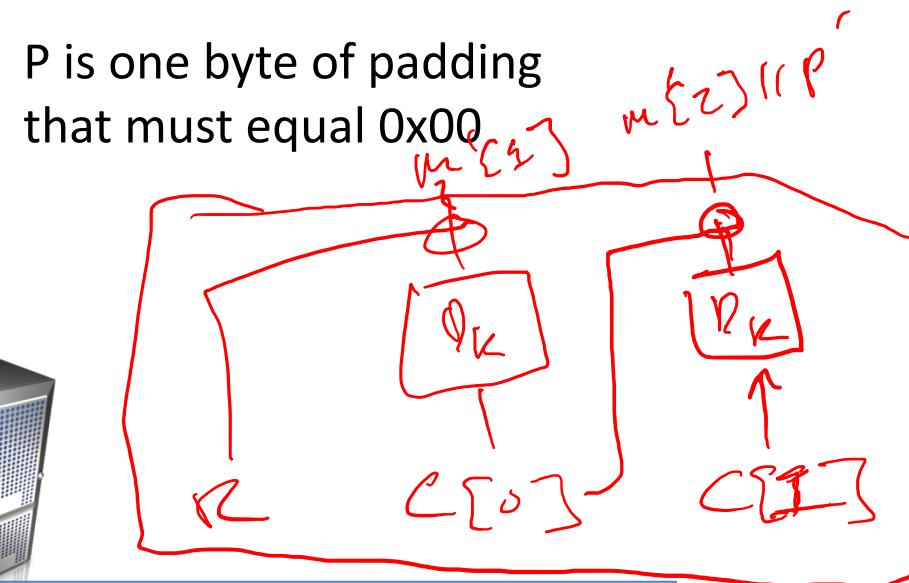

Adversary obtains ciphertext $C[0], C[1], C[2]$
Let R be arbitrary n bits

$R, C[0], C[1]$
error
 $R, C[0] \oplus 1, C[1]$
error
 $R, C[0] \oplus 2, C[1]$
error
...
 $R, C[0] \oplus i, C[1]$
ok

Assume that
 $M[1] || M[2]$ has length
 $2n-8$ bits

P is one byte of padding
that must equal 0x00

Dec(K, C')
 $M'[1] || M'[2] || P' = \underline{\text{CBC-Dec}(K, C')}$
If $P' \neq 0x00$ then
Return error
Else
Return ok

PKCS #7 Padding

$$\text{PKCS#7-Pad}(M) = M || \underbrace{P || \dots || P}_{P \text{ repetitions of byte encoding number of bytes padded}}$$

Possible paddings:

01

02 02

03 03 03

04 04 04 04

...

FF FF FF FF ... FF

For block length of 16 bytes, don't need more than 16 bytes
of padding (10 10 ... 10)

Decryption (assuming at most one block of padding)

Dec(K, C)

$M[1] \parallel \dots \parallel M[m] = \text{CBC-Dec}(K, C)$

$P = \text{RemoveLastByte}(M[m])$

while $i < \text{int}(P)$:

$P' = \text{RemoveLastByte}(M[m])$

 If $P' \neq P$ then

 Return error

Return ok

“ok” / “error” stand-ins for some other behavior:

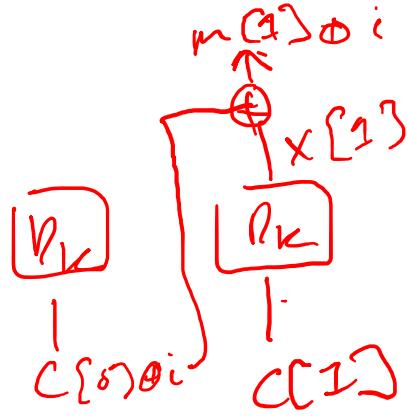

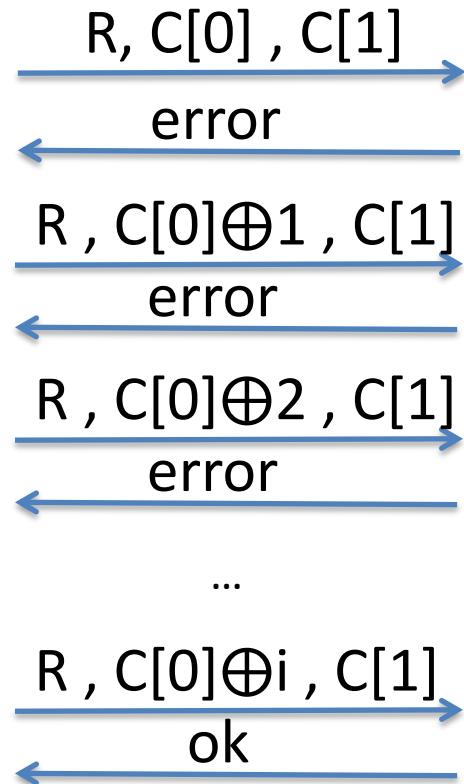

- Passing data to application layer (web server)
- Returning other error code (if padding fails)

PKCS #7 padding oracles

Low byte of $M[1]$ most likely equals $i \oplus 01$

Adversary obtains ciphertext $C[0], C[1], C[2]$
Let R be arbitrary n bits

Dec(K, C)

$M'[1] || \dots || M'[m] = \text{CBC-Dec}(K, C)$

$P = \text{RemoveLastByte}(M'[m])$

while $i < \text{int}(P)$:

$P' = \text{RemoveLastByte}(M'[m])$

If $P' \neq P$ then

[+]

Return error

Return ok

Why? Let $X[1] = D(K, C_1)$

$$C[0][16] \oplus X[1][16] = M[1][16]$$

$$C[0][16] \oplus i \oplus X[1][16] = 01$$

$$M[1][16] \oplus i = 01$$

Actually, it could be that:

$$M[1][16] \oplus i = 02$$

Implies that $M[1][15] = 02$

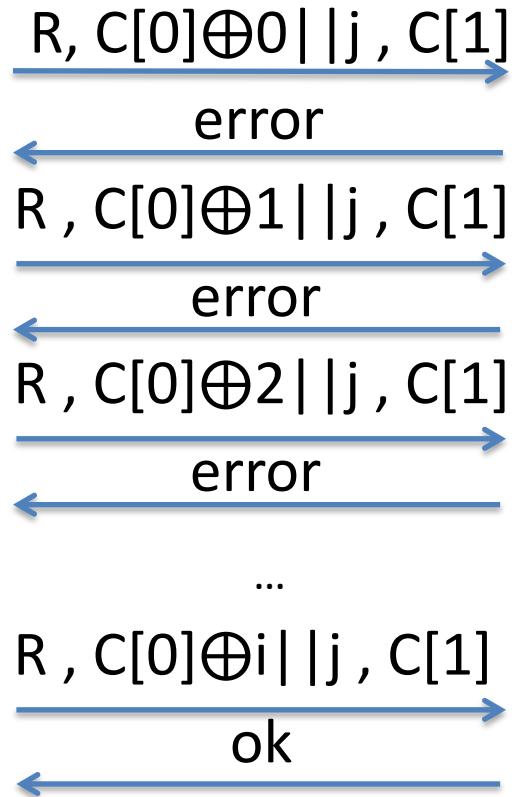

We can rule out with an additional query

PKCS #7 padding oracles

Second lowest byte of
M[1] equals $i \oplus 02$

Adversary
obtains
ciphertext
 $C[0], C[1], C[2]$
Let R be arbitrary
n bits

Dec(K, C)

$M'[1] || \dots || M'[m] = \text{CBC-Dec}(K, C)$

$P = \text{RemoveLastByte}(M'[m])$

while $i < \text{int}(P)$:

$P' = \text{RemoveLastByte}(M'[m])$

If $P' \neq P$ then

$i++$ Return error

Return ok

Set $j = M[1][16] \oplus 01 \oplus 02$

Keep going to recover entire block of message M[1]
Can repeat with other blocks M[2], M[3], ...
Worst case: $256 * 16$ queries per block

Can we change decryption implementation?

Dec(K, C)

$M[1] \parallel \dots \parallel M[m] = \text{CBC-Dec}(K, C)$

$P = \text{RemoveLastByte}(M[m])$

while $i < \text{int}(P)$:

$P' = \text{RemoveLastByte}(M[m])$

 If $P' \neq P$ then

 Return error

Return ok

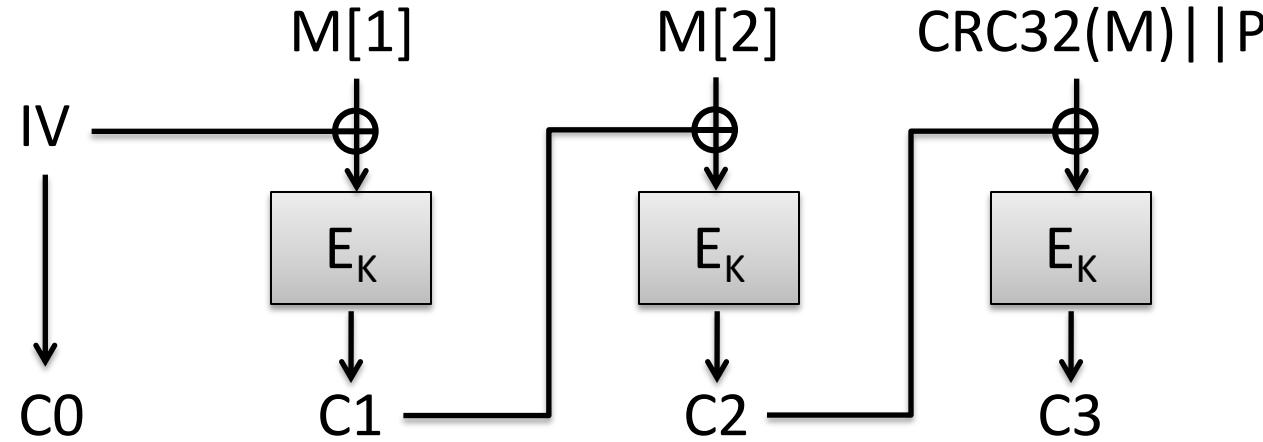

“ok” / “error” stand-ins for some other behavior:

- Passing data to application layer (web server)
- Returning other error code (if padding fails)

Chosen ciphertext attacks against CBC

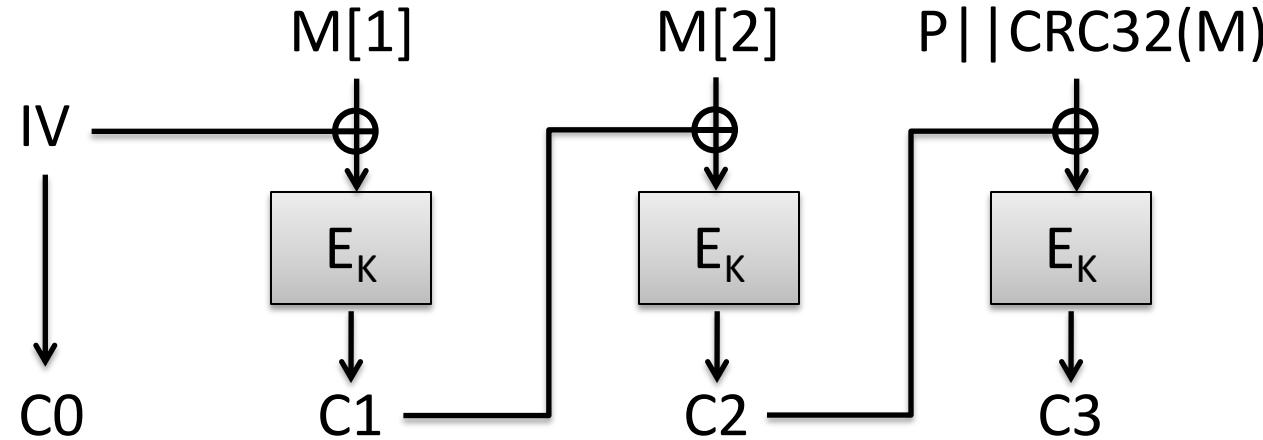

Attack	Description	Year
Vaudenay	10's of chosen ciphertexts, recovers message bits from a ciphertext. Called "padding oracle attack"	2001
Canvel et al.	Shows how to use Vaudenay's ideas against TLS	2003
Degabriele, Paterson	Breaks IPsec encryption-only mode	2006
Albrecht et al.	Plaintext recovery against SSH	2009
Duong, Rizzo	Breaking ASP.net encryption	2011
Jager, Somorovsky	XML encryption standard	2011
Duong, Rizzo	"Beast" attacks against TLS	2011
AlFardan, Paterson	Attack against DTLS	2012
AlFardan, Paterson	Lucky 13 attack against DTLS and TLS	2013
Albrecht, Paterson	Lucky microseconds against Amazon's s2n library	2016

Non-cryptographic checksums?

$CRC32(M)$ is cyclic redundancy code checksum.
Probabilistically catches random errors
Decryption rejects if checksum is invalid

Non-cryptographic checksums?

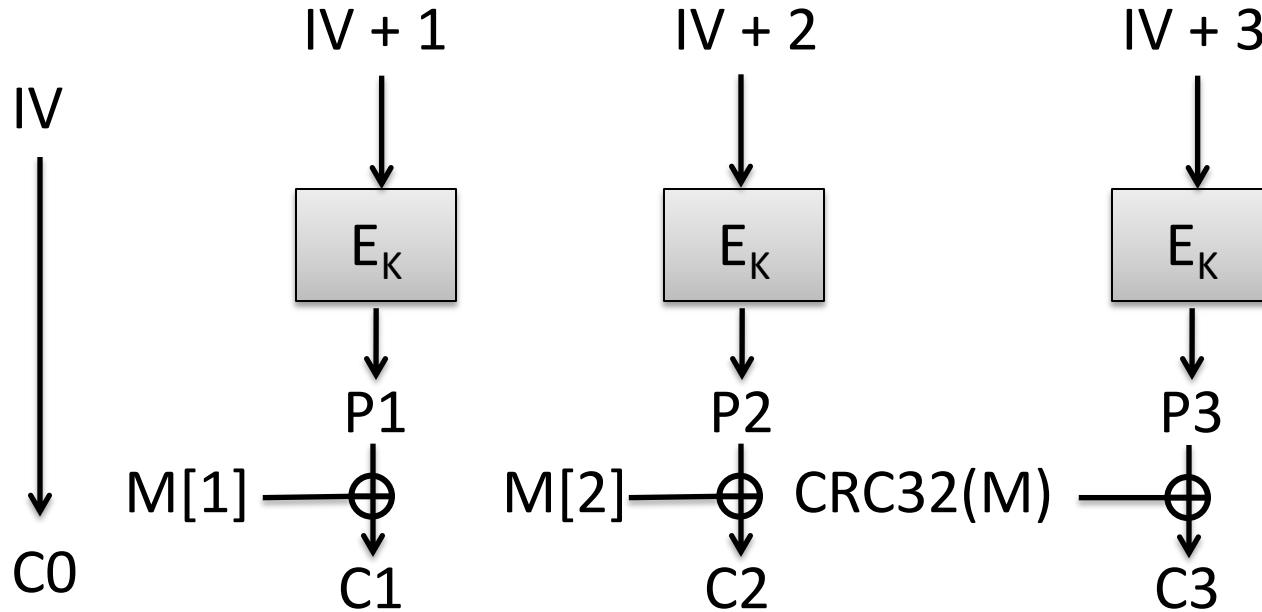

CRC32(M) is cyclic redundancy code checksum.

Probabilistically catches random errors

Decryption rejects if checksum is invalid

Wagner sketched partial chosen plaintext, chosen ciphertext attack
(see Vaudenay 2002 paper)

Non-cryptographic checksums?

Can simply maul message and CRC32 checksum to ensure correctness

None of these modes secure for general-purpose encryption

- CTR mode and CBC mode fail in presence of active attacks
 - Cookie example
 - Padding oracle attacks
- Two types of failure:
 - Integrity (trick recipient into accepting wrong message)
 - Confidentiality (padding oracle attacks)
- Need authentication mechanisms to help prevent chosen-ciphertext attacks

Brief digression: need for per-message randomness

- CTR mode uses a per-message random IV
- Deterministic symmetric encryption:
 - $\text{Enc}(K, M) = \text{Enc}(K, M')$ iff $M = M'$
 - In other words, ciphertexts leak (at least) plaintext equality
 - ECB mode is an old, deprecated example. Leaks *much more* than plaintext equality
 - Other examples in wider use that leak just if $M = M'$:
 - format-preserving encryption (FPE), synthetic IV mode (SIV), ...
 - Must be very careful using these, as repetitions can be useful for *frequency analysis*
